Data Collection - SpaceX API

Use of spacex api

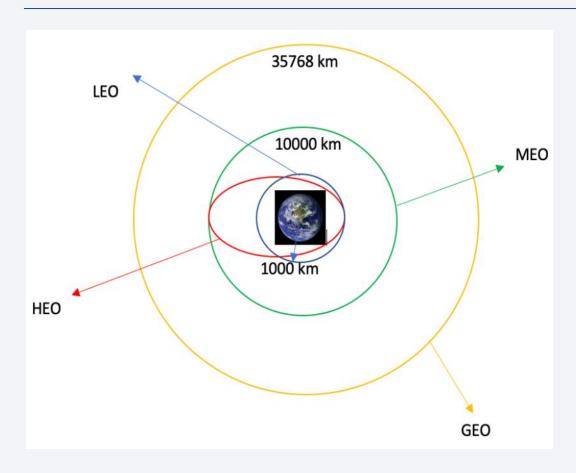

```
1. Get request for rocket launch data using API
          spacex_url="https://api.spacexdata.com/v4/launches/past"
          response = requests.get(spacex url)
   2. Use json_normalize method to convert json result to dataframe
In [12]:
           # Use json normalize method to convert the json result into a dataframe
           # decode response content as json
           static json df = res.json()
In [13]:
           # apply json normalize
           data = pd.json normalize(static json df)
   3. We then performed data cleaning and filling in the missing values
In [30]:
          rows = data_falcon9['PayloadMass'].values.tolist()[0]
          df rows = pd.DataFrame(rows)
          df_rows = df_rows.replace(np.nan, PayloadMass)
          data falcon9['PayloadMass'][0] = df rows.values
          data falcon9
```

Data Collection - Scraping

Scraped data

```
1. Apply HTTP Get method to request the Falcon 9 rocket launch page
       static_url = "https://en.wikipedia.org/w/index.php?title=List_of_Falcon_9_and_Falcon_Heavy_launches&oldid=1027686922"
In [5]: # use requests.get() method with the provided static_url
           # assign the response to a object
          html data = requests.get(static url)
          html_data.status_code
Out[5]: 200
    2. Create a BeautifulSoup object from the HTML response
In [6]: # Use BeautifulSoup() to create a BeautifulSoup object from a response text content
           soup = BeautifulSoup(html_data.text, 'html.parser')
          Print the page title to verify if the BeautifulSoup object was created properly
          # Use soup.title attribute
           soup.title
          <title>List of Falcon 9 and Falcon Heavy launches - Wikipedia</title>
    3. Extract all column names from the HTML table header
         column names = []
          # Apply find all() function with "th" element on first launch table
          # Iterate each th element and apply the provided extract column from header() to get a column name
          # Append the Non-empty column name ('if name is not None and Len(name) > 0') into a list called column names
          element = soup.find_all('th')
          for row in range(len(element)):
                 name = extract_column_from_header(element[row])
                 if (name is not None and len(name) > 0):
                    column names.append(name)
             except:
    4. Create a dataframe by parsing the launch HTML tables
    5. Export data to csv
```

Data Wrangling

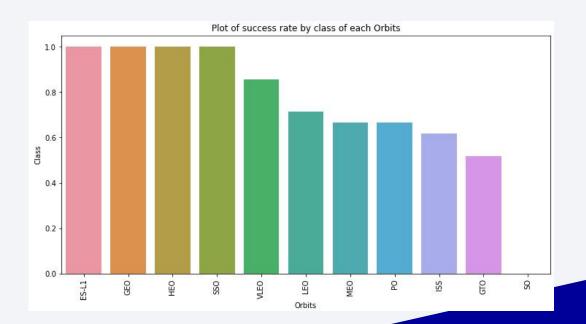

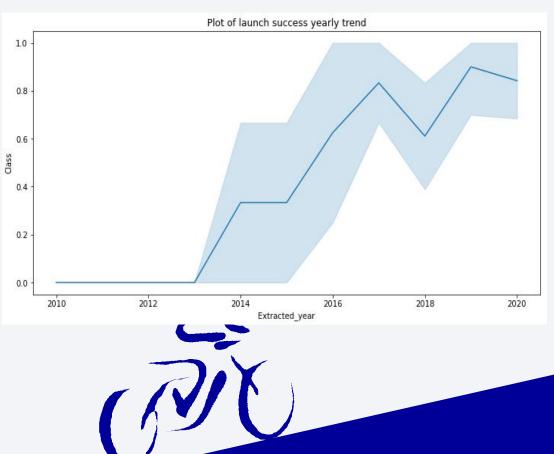

• Exploratory data analysis performed.

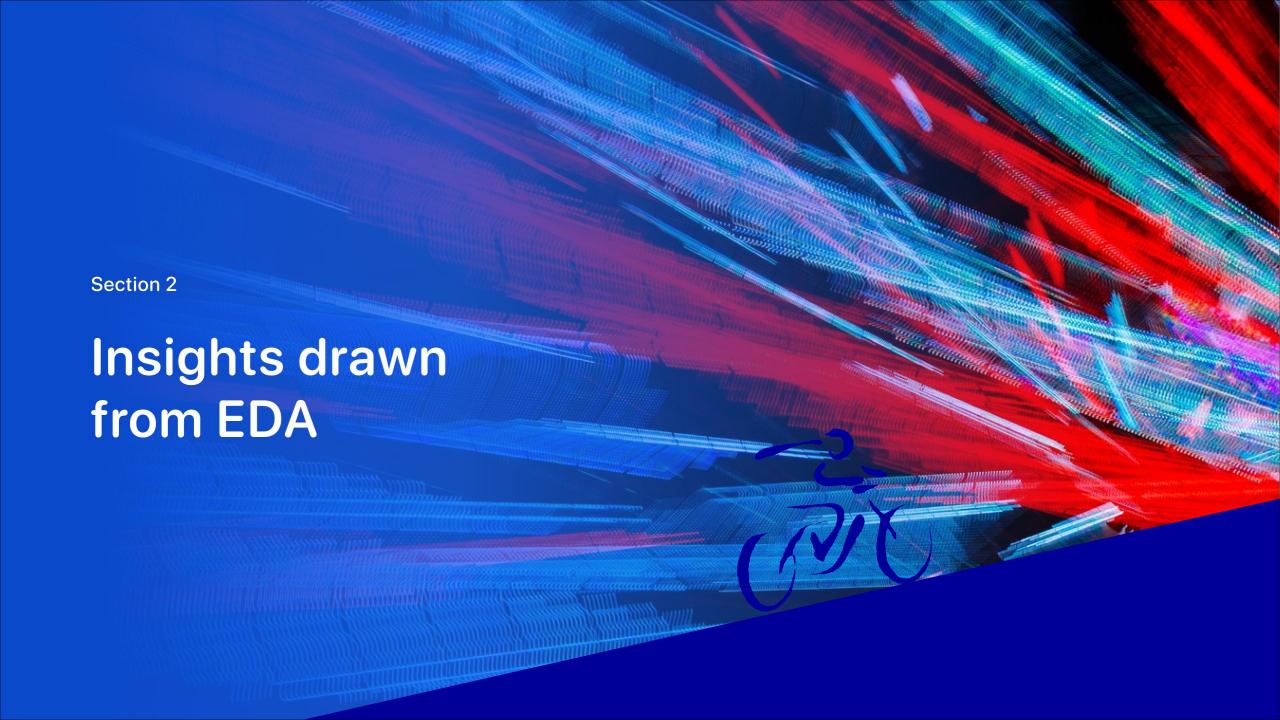

EDA with Data Visualization

• The following images the clear info on payloads at their the place it was launcheds and much more.

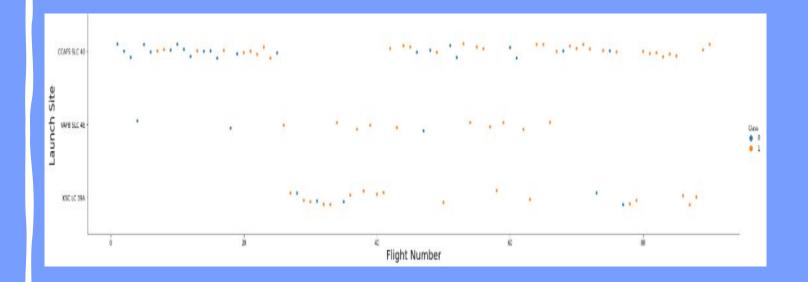

Flight Number and place it was launched

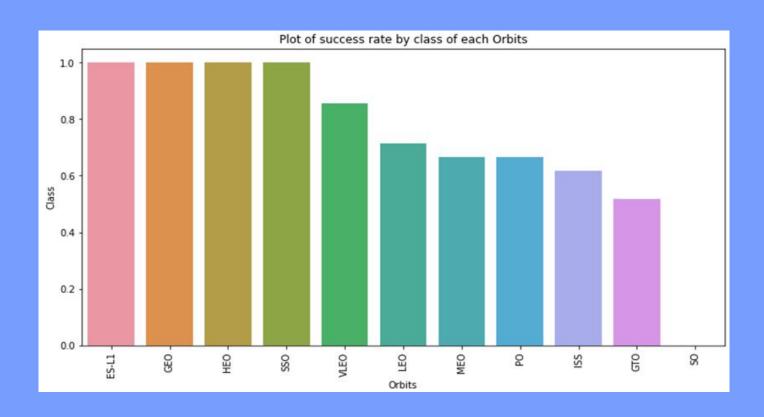

Payload and the the place it was launched

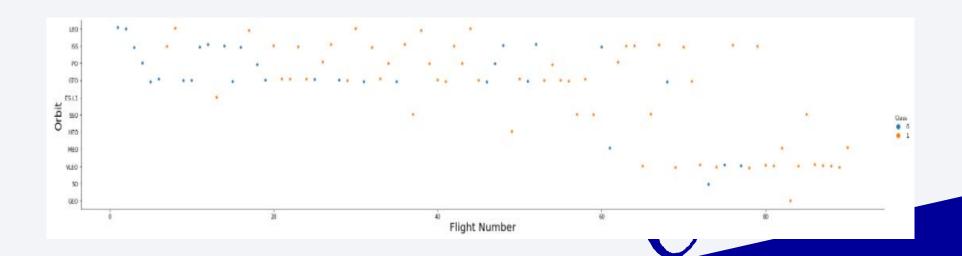

The greater the payload mass for launch site CCAFS SLC 40 the higher the success rate for the rocket.

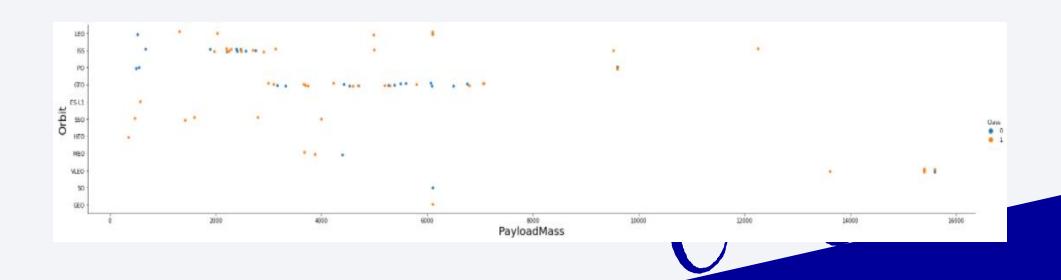

Success of the rocket and the excursion

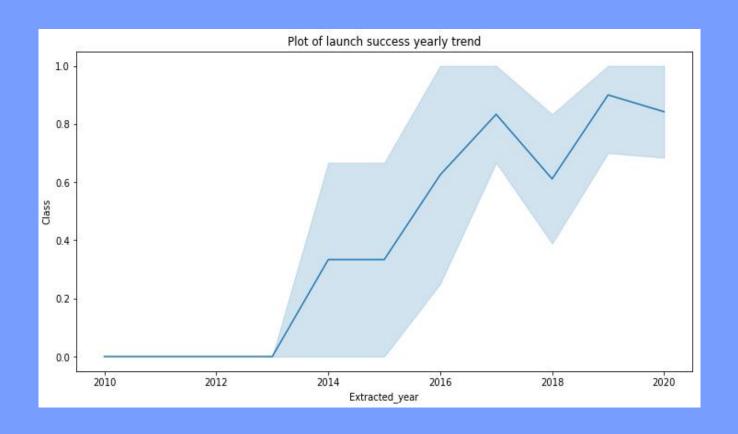

Flight Number and the excursion

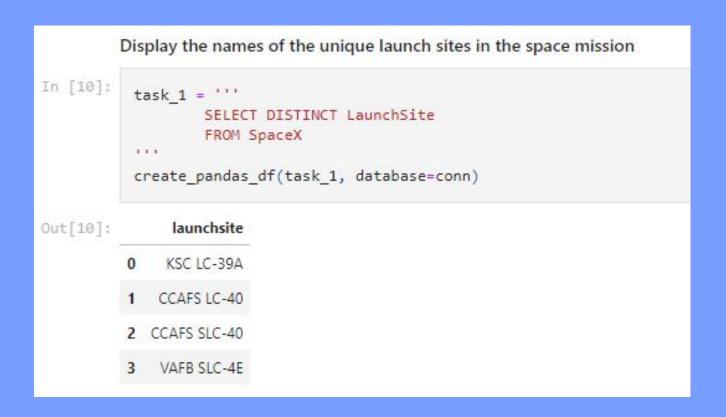

Payload and the exursion

Launch perfection in recent years

All the place it was launched Names

the place it was launched Names Begin with 'CCA'

11]:		FROM WHEN	ECT * 1 SpaceX RE Launc IT 5	hSite LIKE 'CC

                Controlled (ocean)
              Uncontrolled (ocean)
          6 Precluded (drone ship)
                Failure (parachute)
```

All the place it was launcheds global map markers

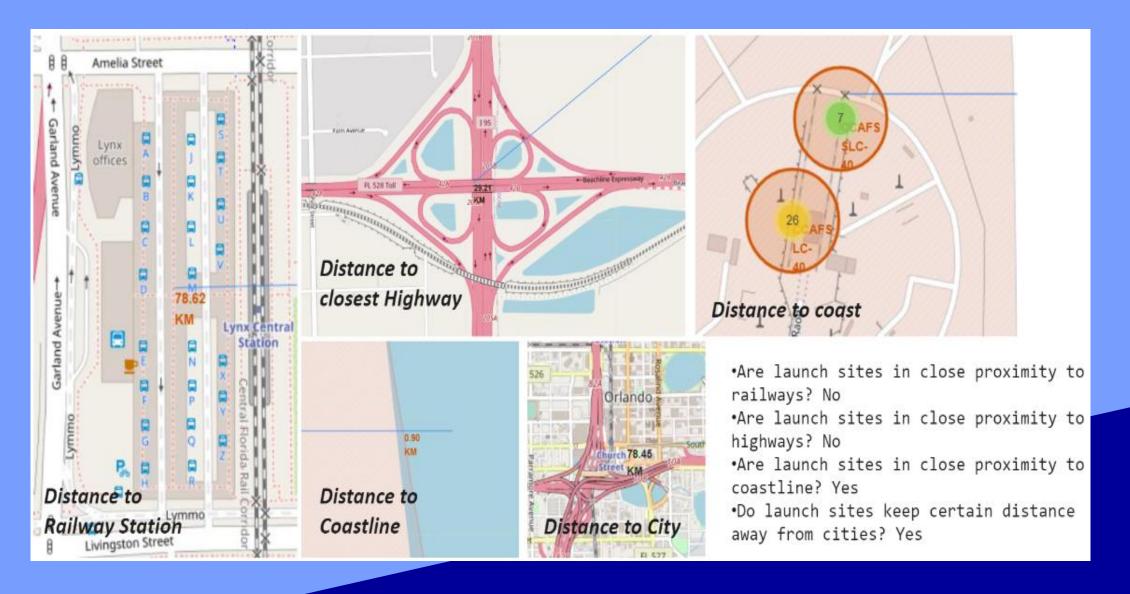

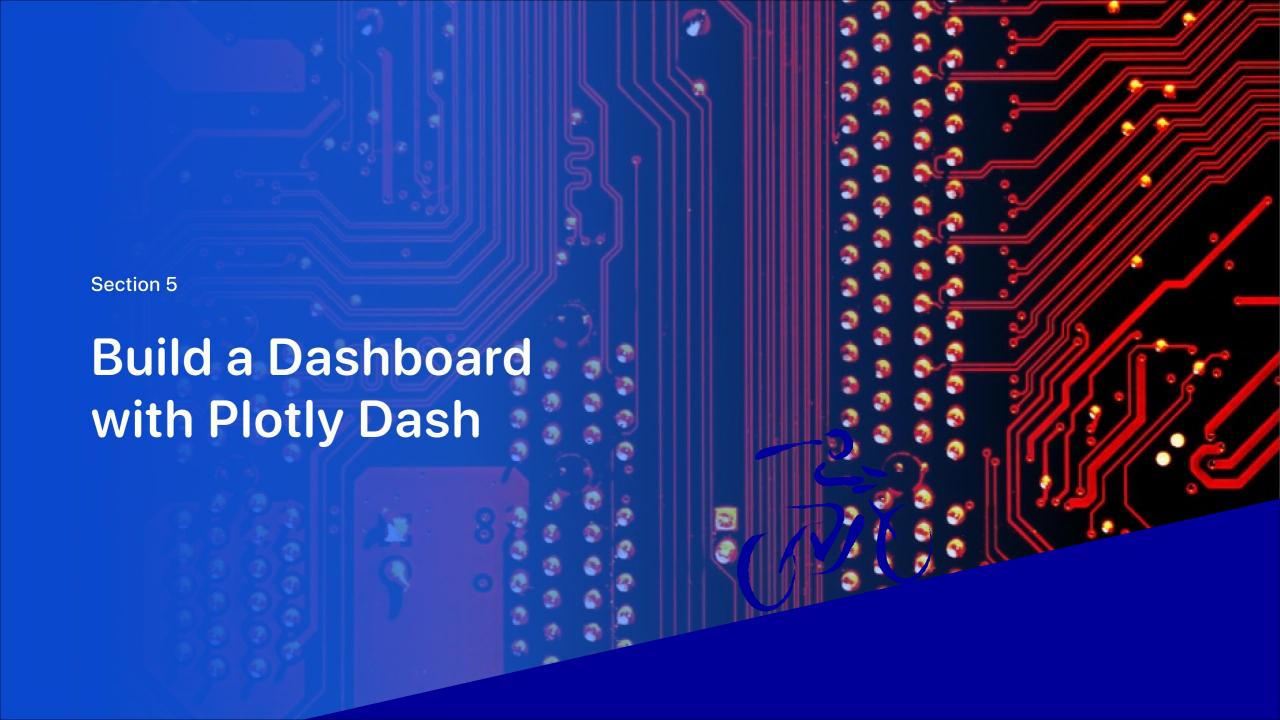

Markers showing the place it was launcheds with color labels

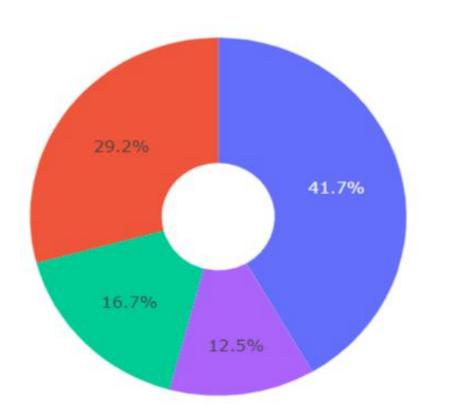

the place it was launched distance to landmarks

Pie chart

KSC LC-39A

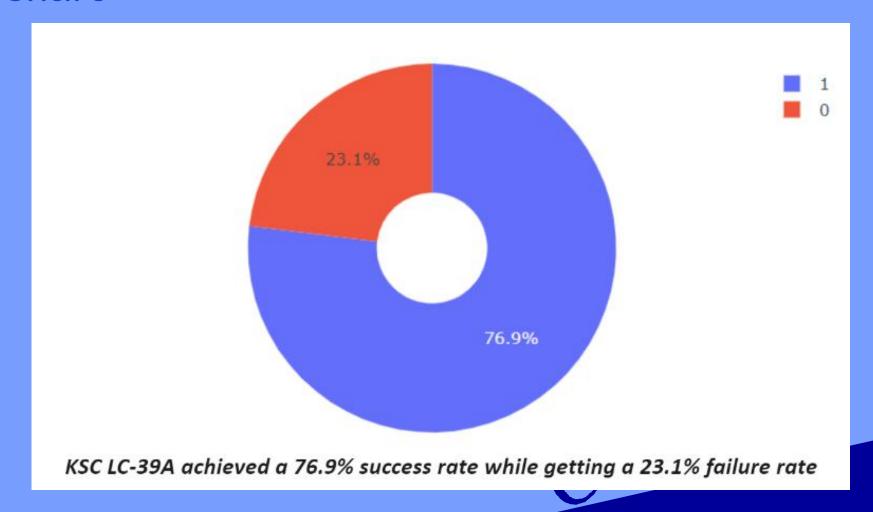

CCAFS LC-40

VAFB SLC-4E

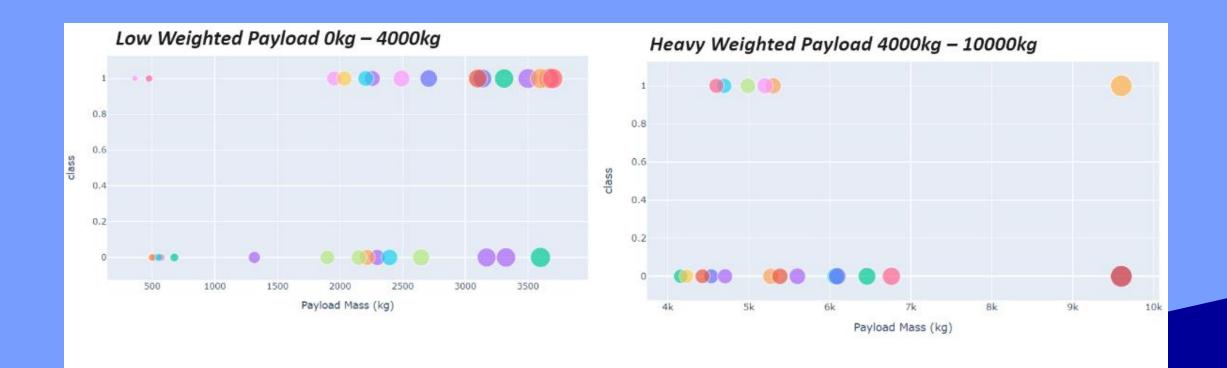

CCAFS SLC-40

We can see that KSC LC-39A had the most successful launches from all the sites

Pie chart

Scatter plot

We can see the success rates for low weighted payloads is higher than the heavy weighted payloads
